(Dated: July 7, 2011)

In this paper we link the physics of topological non-linear σ models with that of Chern-Simons insulators. We show that corresponding to every $2n$ -dimensional Chern-Simons insulator there is a $(n-1)$ -dimensional topological non-linear σ model with the Wess-Zumino-Witten term. Breaking internal symmetry in these non-linear σ models leads to non-linear σ models with the θ term. [This is analogous to the dimension reduction leading from $2n$ -dimensional Chern-Simons insulators to $(2n-1)$ and $(2n-2)$ -dimensional topological insulators protected by discrete symmetries.] The correspondence described in this paper allows one to derive the topological term in a theory involving fermions and order parameters (we shall refer to them as “fermion- σ models”) when the conventional gradient expansion method fails. We also discuss the quantum number of solitons in topological non-linear σ model and the electromagnetic action of the $(2n-1)$ -dimensional topological insulators. Throughout the paper we use a simple model to illustrate how things work.

I. INTRODUCTION

In the past couple of years the topic of topological band insulators (TBI) protected by time reversal symmetry¹⁻⁶ has attracted considerable interests. These insulators are described by free fermion Hamiltonians whose band structure are topologically non-trivial. (Because the mean-field quasiparticle Hamiltonian of a superconductor is also a free fermion theory, the notion of topological band insulator can be simply generalized to include “topological superconductors”⁷⁻⁹.) Two and three dimensional TBI with Dirac-like edge/surface band(s) have been predicted¹⁰⁻¹² and discovered¹³⁻¹⁷. In addition, a classification of TBI in different spatial dimensions has been achieved^{8,9,18}. A dimensional reduction scheme that allows one to generate lower dimensional TBI from even-dimensional Chern-Simons insulators has been established^{18,19}.

On a different front, the effects of topological terms on the dynamics of Goldstone modes and the quantum number of solitons and instantons in non-linear σ (NL σ) models have a long history, and continue to attract strong interests from the physics community²⁰. One of the earliest examples is the charge associated with the solitons of the Peierls-Fröhlich order parameter in one-dimensional charge (bond) density wave systems²¹⁻²⁴. This arises when the fermion field, which couples to a topologically non-trivial order parameter profile, is integrated out. In terms of the fermion spectrum this amounts to the presence of in-gap eigenstates (or in short zero modes) localized on the soliton. Another well-known example is the θ -term in the non-linear σ model describing one dimensional antiferromagnetic spin chains²⁵. There, depending on whether $\theta = \pi$ or $0 \pmod{2\pi}$, the half-integer or integer spin chains are gapless or gapped. In condensed matter physics the appreciation of the physical meaning of various topological terms grows as the number of realization of topological NL σ models increases. For example, recently it is appreciated that, in a NL σ model describing competing orders, one of the effects of the Wess-Zumino-

Witten (WZW) term is to make the topological defects of an order parameter to carry the quantum number of its competition order parameter²⁶⁻²⁹.

In many-body physics one often encounters Lagrangians which are quadratic in the fermion fields, and in which some fermion bilinears couple to space-time dependent order parameters. This type of action can be viewed as the “fluctuation-corrected mean-field theory” of an interacting fermion problem. In a seminal paper Abanov and Wiegmann³⁰ gave a systematic derivation of several kinds of topological terms and soliton quantum numbers when the fermions in such fermion- σ models are integrated out. Their method is designed for models where, without the order parameter, the fermions have a *gapless Dirac* spectrum. The order parameters introduce various types of “mass term” (i.e., fermion bi-linears) each of which can gap out the Dirac node(s). Under the condition where the number of such mass terms is right, and when the mass matrices anti-commute with the Dirac matrices and with one another, a topological term (which is a pure imaginary term in the Euclidean action) is generated upon integrating out the fermions. The topological term can fundamentally affect the ground state properties and the low energy dynamics of the order parameters. However, in condensed matter physics gapless systems are not always described by the massless Dirac theory. For these systems the method presented in Ref. 30 may not work and a more general approach is desired. Moreover, on a conceptual level, it will be very satisfying to understand the relation between two of the areas in topological condensed matter physics: the topological band insulators and the topological NL σ models. This paper serves to fulfill these goals. The main result of this paper can be summarized as follows.

Let H_0 be a translationally-invariant free fermion Hamiltonian defined on a $(n-1)$ -dimensional lattice system. Now let us add fermion bilinears that couple to a set of $(n+2)$ space-time dependent order parameters $m_a(\vec{x}, t)$ ($a = 1, \dots, n+2$), and hence produce the follow-

ing Euclidean action:

$$S = \int dt \left[\sum_i \psi_i^\dagger \partial_t \psi_i + H_0 + \sum_{a=1}^{n+2} \sum_{i,j} m_a(\vec{x}, t) \psi_i^\dagger(t) M_{ij}^a \psi_j(t) \right] \quad (1)$$

where i, j label the lattice sites and $\vec{x}$ is the averaged position of site i and j ; $\psi_i^\dagger = (\psi_{i1}^\dagger, \dots, \psi_{iD}^\dagger)$ are D fermion creation operators on site i . We will focus on local coupling so that the $D \times D$ matrices M_{ij}^a vanish sufficiently fast as sites i and j get further apart. The question we are interested in answering is under what condition a WZW term for the m_a 's will be generated upon integrating out the fermions. In the case where H_0 possesses a gapless Dirac spectrum the answer is provided by Ref. [30]. More explicitly, if the low energy and long wavelength physics in the continuum limit is described by the following action

$$S = \int dt d^d x \left[\psi^\dagger \partial_t \psi + \sum_{\alpha=1}^{n-1} \psi^\dagger (-i \partial_\alpha \Gamma^\alpha) \psi + \sum_{a=1}^{n+2} m_a(\vec{x}, t) \psi^\dagger M^a \psi \right], \quad (2)$$

where Γ^α 's are anti-commuting matrices namely $\{\Gamma^\alpha, \Gamma^\beta\} = 2\delta^{\alpha\beta}$ and M^a are constant mass matrices. The condition for the generation of the WZW term is when the matrices Γ^α 's and the mass matrices M^a 's satisfy

$$\text{Tr} [\Gamma^{\alpha_1} \dots \Gamma^{\alpha_{n-1}} M^{a_1} \dots M^{a_{n+2}}] \propto \epsilon^{\alpha_1 \dots \alpha_{n-1} a_1 \dots a_{n+2}}, \quad (3)$$

Here ϵ is a totally anti-symmetric tensor.

Gapless but non-Dirac dispersions often appear in condensed matter systems. For instance, H_0 can describe quadratic or high order band touching, or even possesses a Fermi surface. For these cases under what condition will a WZW term be generated upon integrating out fermions?

In this paper we shall show that if integrating out the fermion field in Eq. (1) generates a level k WZW term

$$S_{WZW} = -i \frac{2\pi k}{\text{Area}(S^{n+1})} \int_0^1 du \int dt d^{n-1} x \epsilon^{a_1 \dots a_{n+2}} \times n_{a_1} \partial_u n_{a_2} \partial_0 n_{a_3} \partial_1 n_{a_4} \dots \partial_{n-1} n_{a_{n+2}}, \quad (4)$$

where $n_a = m_a / \sqrt{\sum_b m_b^2}$, then there exists a finite range of λ where the following Bloch Hamiltonian

$$H(k_1, \dots, k_{n-1}; p_1, \dots, p_{n+1}) = H_0(k_1, \dots, k_{n-1}) + \lambda \sum_{a=1}^{n+2} m_a(p_1, \dots, p_{n+1}) M^a(k_1, \dots, k_{n-1}) \quad (5)$$

describe a $2n$ -dimensional Chern-Simons insulator, so long as the Pontryagin index³¹ P of the map

$$(p_1, \dots, p_{n+1}) \rightarrow (m_1(\vec{p}), \dots, m_{n+2}(\vec{p})) \quad (6)$$

is non-zero. In Eq. (5) $M^a(k_1, \dots, k_{n-1})$ is the Fourier transform of M_{ij}^a . In Eq. (4) an auxiliary coordinate u is introduced so that

$$\begin{aligned} \hat{n}(t, x_1, \dots, x_{n-1}, u=0) &= (0, 0, \dots, 1) \\ \hat{n}(t, x_1, \dots, x_{n-1}, u=1) &= \hat{n}(t, x_1, \dots, x_{n-1}). \end{aligned} \quad (7)$$

The Pontryagin index of the map in Eq. (6) is given by

$$P = \frac{1}{\text{Area}(S^{n+1})} \int \prod_{i=1}^{n+1} dp_i \epsilon^{a_1, \dots, a_{n+1}} \times n_{a_1} \partial_{p_1} n_{a_2} \partial_{p_2} n_{a_3} \dots \partial_{p_{n+1}} n_{a_{n+2}}; \quad (8)$$

and the n -th Chern number characterizing the $2n$ -dimensional Chern-Simons insulator is given by¹⁸

$$C_n = \frac{1}{n! 2^n (2\pi)^n} \int d^{2n} k \epsilon^{i_1 i_2 \dots i_{2n}} \text{Tr} [f_{i_1 i_2} f_{i_3 i_4} \dots f_{i_{2n-1} i_{2n}}], \quad (9)$$

in which f_{ij} is the momentum space Berry curvature associated with the occupied bands. We emphasize that the above result is valid regardless of whether the gapless Hamiltonian H_0 is Dirac-like or not. Of course once we derived the WZW term, other topological NL σ model can be obtained by breaking the internal $O(n+2)$ symmetry. In this way a link between the topological NL σ models and Chern-Simons insulators is established.

Conversely if Eq. (5) describes a Chern-Simons insulator for a range of λ , it is possible to pick an appropriately bounded order parameter field $\vec{m}(t, \vec{x})$, so that the fermion NL σ model given in Eq. (1) has a WZW term upon fermion integration. The readers are referred to appendix A for a proof of the above correspondence.

Actually, the connection between $2n$ -dimensional Chern-Simons insulators and $(n-1)$ -dimensional topological NL σ models discussed above is a special case of the following more general relation. Consider a $2n$ -dimensional Bloch Hamiltonian describing a Chern-Simons insulators with a nonzero C_n for a finite range of λ ($0 < \lambda < \lambda^*$)

$$H(k_1, \dots, k_{n-1}; p_1, \dots, p_{n+1}) = H_0(k_1, \dots, k_{n-1}) + V(k_1, \dots, k_{n-1}; \lambda m_1(p_1, \dots, p_{n+1}), \dots, \lambda m_{n+2}(p_1, \dots, p_{n+1})). \quad (10)$$

If the map $(p_1, \dots, p_{n+1}) \rightarrow (m_1, \dots, m_{n+2})$ has a nonzero pontryagin index P , then the following steps generate a $(n-1)$ -dimensional fermion- σ model which yields a level $k = C_n/P$ WZW term upon integrating out the fermions. (i) Perform the Fourier transform with respect to $k_1, \dots, k_{n-1}$ to rewrite Eq. (10) in real space. (ii) Replace $m_a(p_1, \dots, p_{n+1})$ with an appropriately bounded space-time dependent fields $m_a(t, \vec{x})$.

The correspondence discussed above establishes a link between topological $NL\sigma$ models and Chern-Simons insulators. It also allows one to determine whether integrating out fermion field generates topological terms in the $NL\sigma$ model describing the order parameter dynamics when the conventional gradient expansion of in Ref. [30] fails. The rigorous proof for the above correspondence is presented in appendix A.

In the rest of the paper we shall use a simple model to illustrate the principal ideas. It turns out that for this simple model the Abanov-Wiegmann method does not work, consequently the scheme we discussed above is necessary to derive its WZW term.

II. A SIMPLE MODEL WITH QUADRATIC BAND TOUCHING (QBT)

As a simple example of a gapless Hamiltonian which has a dispersion different from that of massless Dirac fermions we consider the following one dimensional lattice model (this model is motivated by the spectrum of bilayer graphene). The schematic representation of the model is shown in Fig. 1(a). Here black and red indicate strong and weak bonds respectively. The vertical blue bonds have the strongest hopping. There are four sites per unit cell and the 4×4 Bloch Hamiltonian is given by

$$H(k) = \begin{pmatrix} 0 & A & T_{13}(k) & 0 \\ A & 0 & 0 & T_{24}(k) \\ T_{13}^*(k) & 0 & 0 & 0 \\ 0 & T_{24}^*(k) & 0 & 0 \end{pmatrix} \quad (11)$$

where $T_{13}(k) = (1 - \delta t) + (1 + \delta t)e^{-ik}$ and $T_{24}(k) = (1 + \delta t) + (1 - \delta t)e^{-ik}$. Here $1 \pm \delta t$ and A are the strength of black, red and the vertical bonds respectively. When $\delta t = 0$ and $A = 2$ the dispersion relation is shown in Fig. 1(b). Note that two bands touch *quadratically*^{32,33}, at $k = \pi$. When $A \gg 1$ the Hamiltonian in Eq. (11) can be reduced to an effective 2×2 Hamiltonian by performing second order perturbation theory to remove the strongly hybridizing vertical bonds. The result is given

by

$$-\frac{4}{A} \begin{pmatrix} 0 & (\cos \frac{k}{2} + i\delta t \sin \frac{k}{2})^2 \\ (\cos \frac{k}{2} - i\delta t \sin \frac{k}{2})^2 & 0 \end{pmatrix} \quad (12)$$

The corresponding dispersion is shown in part (c) of Fig. 1. In the following we shall multiply the Hamiltonian in Eq. (12) by $-\frac{A}{2}$ and consider the effective model

$$\begin{aligned} H(k) &= 2 \begin{pmatrix} 0 & (\cos \frac{k}{2} + i\delta t \sin \frac{k}{2})^2 \\ (\cos \frac{k}{2} - i\delta t \sin \frac{k}{2})^2 & 0 \end{pmatrix} \\ &= [(1 - \delta t^2) + (1 + \delta t^2) \cos k] \tau_1 - [2\delta t \sin k] \tau_2. \end{aligned} \quad (13)$$

One might argue that the QBT point can be viewed as two Dirac points merged together. Hence upon integrating out fermions one can still apply the method of Ref. [30], and sum the results associated with each Dirac point at the end. This is in fact not generally true even though there are cases the conventional gradient expansion work³⁴. As the Dirac point merges, the momentum range with linear dispersion vanishes. After the Dirac points merge the length scale above which one can think of the system as two separated Dirac points diverge. It is therefore by no means clear that one can simply sum the results assuming the Dirac points are separated to determine those for the QBT model.

III. THE SOLITON OF THE QBT MODEL

A. The Jackiw-Rebbi soliton

Setting $\delta t \neq 0$ in Eq. (13) opens a gap in the dispersion (Fig. 2(a)). In the classic work of Jackiw and Rebbi²¹ it was shown that in a soliton mass background, the one-dimensional Dirac Hamiltonian exhibits one mid-gap state per soliton. When we let the gap parameter δt in Eq. (13) to assume a soliton profile (see Fig. 2(b)) mid-gap states appear in the energy spectrum (Fig. 2(c)). However unlike the Dirac Hamiltonian, there are *two* mid gap states per soliton, as expected for the QBT. It is worth to point out that on this specific lattice the mid-gap states are true zero modes; they are protected by the “chiral” symmetry $\tau_3 H(k) \tau_3 = -H(k)$ in Eq. (13).

B. The zero mode theorem

In this section we prove the zero mode theorem. In order to allow a comparison with the Jackiw-Rebbi zero

FIG. 1: (color on-line)(a) A schematic representation of the QBT model. Here back and red indicate strong and weak bonds respectively. The vertical blue bonds are much stronger any other hopping. (b) The dispersion relation for the special case when the back and red bonds have equal strength. (c) The dispersion of the model in Eq. (13) when the strongly hybridizing dimers are eliminated.

mode theorem²¹, we work in the continuum limit. By expanding Eq. (13) around $k = \pi$ we obtain

$$H(q) = \frac{1}{2} \begin{pmatrix} 0 & (i2\delta t - q)^2 \\ (-i2\delta t - q)^2 & 0 \end{pmatrix}, \quad (14)$$

where $q = k - \pi$. When δt is position-dependent the above Hamiltonian becomes

$$H = \frac{1}{2} \begin{pmatrix} 0 & Q^2 \\ Q^{\dagger 2} & 0 \end{pmatrix} \quad (15)$$

with

$$Q = i2\delta t(x) + i\partial_x. \quad (16)$$

Since the third Pauli matrix, τ_3 , anticommutes with H in Eq. (15), the zero energy eigenfunctions must be eigenvectors of it. Thus they are either of the form $\begin{pmatrix} 0 \\ v(x) \end{pmatrix}$ or $\begin{pmatrix} u(x) \\ 0 \end{pmatrix}$.

Let us first consider the first possibility

$$\begin{pmatrix} 0 & Q^2 \\ Q^{\dagger 2} & 0 \end{pmatrix} \begin{pmatrix} 0 \\ v(x) \end{pmatrix} = 0. \quad (17)$$

In this case $Q^2 v(x) = 0$ and there are two linearly independent solutions, namely,

$$\begin{aligned} v(x) &\sim e^{-2 \int_0^x \delta t(y) dy}, \quad \text{and} \\ v(x) &\sim x e^{-2 \int_0^x \delta t(y) dy}. \end{aligned} \quad (18)$$

FIG. 2: (color on-line)(a) In the presence of a non-zero δt an energy gap opens at the quadratic touching point. Here $\delta t = 0.2$ is used. (b) A soliton $\delta t(x)$ profile. (c) Schematic representation of the energy spectrum associated with a soliton $\delta t(x)$ profile. The red line marks the position of mid-gap soliton states. (d) The eigenfunctions associated with the zero modes.

Note that for the $\delta t(x)$ profile shown in Fig. 2(b) (where the center of the soliton is at $x = 0$) these are decaying solutions as $x \rightarrow \pm\infty$, hence are normalizable. Note that the first line of Eq. (18) is the same as the Jackiw-Rebbi soliton solution. For $\delta t(x) = \delta t_0 \tanh(x/\xi)$ these two solutions are illustrated as the blue and red curves in Fig. 2(d).

The second possibility

$$\begin{pmatrix} 0 & Q^2 \\ Q^{\dagger 2} & 0 \end{pmatrix} \begin{pmatrix} u(x) \\ 0 \end{pmatrix} = 0, \quad (19)$$

yields the solutions

$$\begin{aligned} u(x) &\sim e^{2 \int_0^x \delta t(y) dy}, \quad \text{or} \\ u(x) &\sim x e^{2 \int_0^x \delta t(y) dy}. \end{aligned} \quad (20)$$

For the $\delta t(x)$ profile shown in Fig. 2(b) these two solutions are not normalizable, hence must be rejected.

C. The spectral flow associated with the Goldstone-Wilczek soliton

Goldstone and Wilczek²³ generalized the work of Jackiw and Rebbi²¹ and considered a model with two spatial-dependent mass terms. Viewing the two mass parameters as the components of a 2-vector, they considered the situation where the mass vector rotates as the position x is varied. In the case where the 1D system is a closed ring there are soliton configurations where the mass vector wind integer number of times as x traverses

the ring. In Ref. 30 it is shown that for winding number n the soliton charge is $|\Delta Q| = ne$.

In exactly the same fashion we generalize the QBT model of Eq. (13) to include one more mass term. In the situation where both mass terms (m_1, m_2) are constant, the Hamiltonian read

$$H(k) = 2 \begin{pmatrix} m_2 & (\cos \frac{k}{2} + im_1 \sin \frac{k}{2})^2 \\ (\cos \frac{k}{2} - im_1 \sin \frac{k}{2})^2 & -m_2 \end{pmatrix} \quad (21)$$

m_2 represents the difference of on-site potential between the two chains. First, we let $(m_1, m_2) \rightarrow m(\cos \theta, \sin \theta)$, and plot the energy spectrum of $H(k, \theta)$ as a function of k and θ . The results is shown in Fig. 3(a) where m is chosen to be 0.2. Clearly, for all values of θ there is an energy gap. Next, we consider the case where θ is position-dependent and winds by $2\pi n$ as x traverses the 1D ring. In Fig. 3(b) We show the spectral flow across $E = 0$ as n is varied. (For non-integer n there are spatial discontinuity in the mass terms.) Clearly in every 2π cycle of θ , there are *two* energy levels cross $E = 0$ from above to below. This is in contrast with the Goldstone-Wilczek model²³ where only *one* level crosses $E = 0$ per 2π cycle.

The above spectral flow is summarized by the following term in the imaginary-time effective action

$$S_B = -\frac{i}{2\pi} \times 2 \int dx A_0 \partial_x \theta. \quad (22)$$

The same term with half of the coefficient, i.e., $-\frac{i}{2\pi} \int dx A_0 \partial_x \theta$ was derived first by Goldstone-Wilczek²³, and summarized in Abanov-Wiegmann³⁰ as one of the applications of the gradient expansion method.

Thus, to derive the effective action in Eq. (22), one naturally would attempt to generalize the gradient expansion method to the continuum version of the model studied in this section, namely,

$$H = \begin{pmatrix} 2m_2(x) & (i\partial_x + i2m_1(x))^2 \\ (i\partial_x - i2m_1(x))^2 & -2m_2(x) \end{pmatrix}. \quad (23)$$

D. Beyond the gradient expansion

It is simple to see that a direct application of the gradient expansion method employed previously (e.g. in Ref. 30) does not work for the model in Eq. (23). The problem is rooted in the facts that (1) the two masses m_1 and m_2 do not enter the Hamiltonian on equal footing. Because of this, it is not possible to find a chiral rotation^{35,36} so that locally the mass vector is rotated to a reference value. (2) When we expand $(i\partial_x + i2m_1(x))^2$ the cross term mixes the spatial gradient and $m_1(x)$. In other words, the mass terms

FIG. 3: (color on-line) (a) The energy spectrum of Eq. (21), with $m_1 \rightarrow m \cos \theta, m_2 \rightarrow m \sin \theta$, as a function of k and θ . Notice that for all values of θ there is an energy gap in the 1D dispersion $E(k)$. (b) The spectral flow as a function of the winding number n .

couples with the momentum. Nonetheless, we cannot rule out the possibility that some variant of the gradient expansion method can work for the model in Eq. (23). Instead of finding a variant of the gradient expansion method, we propose a dimension reduction scheme to derive topological terms in fermionic sigma models. The dimension reduction scheme is qualitatively different from the previous gradient expansion method and is a systematic method applicable to fermionic sigma models whose $H_0(\vec{k})$ can have generic fermion dispersions such as massless Dirac, quadratic touching, or even Fermi surfaces.

IV. A 2D CHERN-SIMONS INSULATOR AND THE CORRESPONDING 0D TOPOLOGICAL $NL\sigma$ MODELS

In Ref. 18, Qi, Hughes, and Zhang put forward a dimension reduction scheme which allows one to start from Chern-Simons insulators in even dimensions and obtain lower dimensional topological insulators by treating the extra momentum variables as parameters. Here we take their program one step further and show how to obtain topological fermion- $NL\sigma$ models from dimension reduction. We will point out some qualitative differences between our view and that of Qi *et al* as we go along. Let us start with the relation between a 2D Chern-Simons insulator and the zero-dimensional $NL\sigma$ models as a warm up.

FIG. 4: (color on-line) Left panel: the image of $k_1 \in [0, 0.95\pi], k_2 \in [0, 2\pi]$. Right panel: the image of $k_1 \in [\pi, 1.95\pi], k_2 \in [0, 2\pi]$. We deliberately removed two small intervals in k_1 , namely, $(0.95\pi, \pi)$ for the left and $(1.95\pi, 2\pi)$ for the right panel, to reveal the origin (red dot) where H is degenerate.

A. From the QBT model to a two-dimensional Chern-Simons insulator

From Fig. 3(a) we see that by regarding θ as the momentum in an extra dimension, the bandstructure is that of a 2D insulator. What is less obvious is that this insulator is a Chern-Simons (or Hall) insulator with $\sigma_{xy} = \frac{2}{2\pi}$, or equivalently with the first Chern number (TKNN index³⁷) $C_1 = 2$. This can be shown by directly computing the first Chern number

$$C_1 = \frac{1}{2\pi} \int_{BZ} d^2k \epsilon^{ij} \frac{\langle u_{\mathbf{k}} | \partial_{k_i} H(\mathbf{k}) | v_{\mathbf{k}} \rangle \langle v_{\mathbf{k}} | \partial_{k_j} H(\mathbf{k}) | u_{\mathbf{k}} \rangle}{(E_u(\mathbf{k}) - E_v(\mathbf{k}))^2} \quad (24)$$

associated with the insulator described by

$$H(\mathbf{k}) = 2 \begin{pmatrix} m \sin k_2 & [\cos \frac{k_1}{2} + im \cos k_2 \sin \frac{k_1}{2}]^2 \\ [\cos \frac{k_1}{2} - im \cos k_2 \sin \frac{k_1}{2}]^2 & -m \sin(k_2) \end{pmatrix}. \quad (25)$$

In Eq. (24) $i, j = 1, 2$ and u and v labels the occupied and unoccupied bands, respectively. More pictorially we can expand the 2×2 Hamiltonian in Eq. (25) as the linear combination of three Pauli matrices, and view the combination coefficients as the coordinates in R^3 . In this way we have constructed a mapping from the Brillouin zone $k_{1,2} \in [0, 2\pi)$ to R^3 . In Fig. 4 we illustrate this mapping. The left panel corresponds to the image of $k_1 \in [0, 0.95\pi], k_2 \in [0, 2\pi]$ and right panel is the image of $k_1 \in [\pi, 1.95\pi], k_2 \in [0, 2\pi]$. We deliberately remove two small intervals in k_1 , namely, $(0.95\pi, \pi)$ and $(1.95\pi, 2\pi)$ to reveal the origin (red dot) where H is degenerate.

Clearly the image is a closed surface, and it wraps around the origin *twice* which implies $C_1 = 2$. If we couple the electromagnetic gauge field to the fermions described by the Hamiltonian in Eq. (25) and integrate out the fermions, the familiar Chern-Simons action will be obtained

$$S_{CS_1} = -\frac{iC_1}{4\pi} \int d^2x dt \epsilon^{\mu\nu\lambda} A_\mu \partial_\nu A_\lambda. \quad (26)$$

This action summarizes the linear response of the Hall insulator.

B. Explaining the spectral flow of the Goldstone-Wilczek soliton

Let us imagine the Hall insulator described by Eq. (25) on a two-torus. We insert a magnetic flux $L_2 \phi(x_1)$ through the second hole of the torus and restrict A_0, A_1 to depend on x_1 and t only. By substituting $A_2 = \phi(x_1)$ and $A_0(x_1, t), A_1(x_1, t)$ into the Chern-Simons action Eq. (26) we obtain

$$S_{CS_1} \rightarrow -\frac{iC_1}{2\pi} L_2 \int dx_1 dt A_0(x_1, t) \partial_1 \phi(x_1). \quad (27)$$

In obtaining Eq. (27) we have taken into account of the fact that the time direction is cyclic. Since none of $A_{0,1}$ and ϕ depend on x_2 , translation in x_2 is a symmetry. As the result, k_2 is a good quantum number, and the system decouples into L_2 number of one dimensional subsystems each characterized by a different k_2 . The tight binding Hamiltonian of these one dimensional systems are given by

$$\begin{aligned}
H_{1D}(k_2) = & \sum_i \psi_i^\dagger \left[2m \sin(k_2 + \phi_i) \tau_3 + (1 - m^2 \cos^2(k_2 + \phi_i)) \tau_1 \right] \psi_i + \sum_i \left[\psi_{i+1}^\dagger \left[\frac{1 + m^2 \cos^2(k_2 + \phi_i)}{2} \tau_1 \right. \right. \\
& \left. \left. + im \cos(k_2 + \phi_i) \tau_2 \right] \psi_i + h.c \right]. \quad (28)
\end{aligned}$$

Here $\psi_i^\dagger = (c_{1i}^\dagger, c_{2i}^\dagger)$, and $\tau_{1,2,3}$ are the Pauli matrices. In the presence of $A_{0,1}(x_1, t)$ each of these one dimensional system contributes an imaginary (Berry phase) effective action S_{1D} which adds up to Eq. (27). Thus

$$\begin{aligned}
& \sum_{k_2} S_{1D}[k_2 + \phi(x_1); A_\alpha(x_1, t)] \\
& = -\frac{iC_1}{2\pi} L_2 \int dx_1 dt A_0(x_1, t) \partial_1 \phi(x_1). \quad (29)
\end{aligned}$$

Eq. (29) implies

$$\begin{aligned}
& S_{1D}[k_2 + \phi(x_1); A_\alpha(x_1, t)] \\
& = -i \frac{c(k_2)}{2\pi} \int dx_1 dt A_0(x_1, t) \partial_1 \phi(x_1), \quad (30)
\end{aligned}$$

where

$$\int_0^{2\pi} \frac{dk_2}{2\pi} c(k_2) = C_1. \quad (31)$$

Now we show that $c(k_2)$ is acutally independent of k_2 . Let us consider the special $k_2 = 0$ case of Eq. (30), and set $\phi(x_1) = \theta(x_1) + k_2$. Under these condition Eq. (30) becomes

$$\begin{aligned}
& S_{1D}[k_2 + \theta(x_1); A_\alpha(x_1, t)] \\
& = -i \frac{c(0)}{2\pi} \int dx_1 dt A_0(x_1, t) \partial_1 \theta(x_1), \quad (32)
\end{aligned}$$

Compare the above result with the $k_2 \neq 0$ case of Eq. (30) we conclude $c(k_2) = c(0)$ is independent of k_2 . Using Eq. (31) we conclude $c(k_2) = C_1, \forall k_2$. Thus

$$S_{1D}[\phi; A_\alpha] = -\frac{iC_1}{2\pi} \int dx_1 dt A_0 \partial_1 \phi. \quad (33)$$

Eq. (33) is the desired topological term specifying the charge of Goldstone-Wilczek soliton, derived without using the gradient expansion. A similar consideration was given in Ref.18, where a *spatial constant* but time dependent k_2 was considered. The authors argued that the quantum Hall effect in 2D translates into quantized charge pumping as the parameter k_2 in the 1D model is varied. In this way they derived $J = \frac{C_1}{2\pi} \frac{d\theta}{dt}$. Then by charge conservation the authors deduced the charge density associated with a spatial dependent θ to be $\frac{C_1}{2\pi} \frac{d\theta}{dx_1}$.

The above method deriving the spectral flow of the Goldstone-Wilczek soliton in 1D can be straightforwardly generalized to higher dimensions. To compute

the fermion number of a topological soliton in a n -dimensional fermion σ model with $n+1$ masses $m_a(t, \vec{x})$, $a = 1, \dots, n+1$, we compute the n -th Chern number C_n of the corresponding $2n$ -dimensional insulator obtained by replacing $m_a(t, x)$ with $m_a(p_1, \dots, p_n)$, where p_i are momenta in the extra dimensions. When the map $(p_1, \dots, p_n) \rightarrow m_a(p_1, \dots, p_n)$ has Pontryagin index P , the fermion number of the fundamental soliton, i.e., soliton whose real-space Pontryagin index is equal to one, is C_n/P . Since the proof of the above statement is similar to the one for the WZW term, we will not present it explicitly.

C. Deducing the existence of edge states in the QBT model

In this section we shall deduce informations concerning the edge properties of the QBT model. We start with the 2D Hall insulator (Eq. (25)) on a torus and adiabatically switch on a spatially independent magnetic flux $L_2 \phi$ in, say, the second hole of the torus. Thus $A_2 \rightarrow \phi$ and, like in the last section, we shall allow $A_{0,1}$ to depend on x_1 and t only. Under these conditions the Chern-Simons effective action becomes

$$S_{CS_1} \rightarrow \frac{iC_1 \phi}{2\pi} L_2 \int dx_1 dt \epsilon^{\alpha\beta} \partial_\alpha A_\beta. \quad (34)$$

On the other hand since the x_2 translation symmetry remains, k_2 is a good quantum number. Hence the action in Eq. (34) is the sum of the Berry phase of an assembly of 1D systems, each characterized by a parameter k_2 , i.e.,

$$\frac{iC_1 \phi}{2\pi} L_2 \int dx_1 dt \epsilon^{\alpha\beta} \partial_\alpha A_\beta = \sum_{k_2} S_{1D}[k_2 + \phi; A_\alpha]. \quad (35)$$

Compare the above result with that obtained by setting ϕ to zero we obtain

$$\begin{aligned}
& \sum_{k_2} (S_{1D}[k_2 + \phi; A_\alpha] - S_{1D}[k_2; A_\alpha]) \\
& = iC_1 \frac{\phi}{2\pi/L_2} \int dx_1 dt \epsilon^{\alpha\beta} \partial_\alpha A_\beta. \quad (36)
\end{aligned}$$

The right hand side of Eq. (36) is a total derivative, and vanishes in the absence of boundary. Since the imaginary time dimension is cyclic, the only chance for it to be non-zero is when the system is open in the x_1 direction. Under

that condition Eq. (36) becomes

$$\begin{aligned} & \sum_{k_2} (S_{1D}[k_2 + \phi; A_\alpha] - S_{1D}[k_2; A_\alpha]) \\ &= -iC_1 \frac{\phi}{2\pi/L_2} \int dt (A_0(L_1, t) - A_0(0, t)) \end{aligned} \quad (37)$$

Perform $i\delta/\delta A_0(L_1, t)$ and $i\delta/\delta A_0(0, t)$ of the right hand side we obtain the extra charge localized on the right and left ends:

$$\begin{aligned} \sum_{k_2} \Delta Q_{\text{right}}(k_2) &= C_1 \frac{\phi}{2\pi/L_2}, \quad \text{and} \\ \sum_{k_2} \Delta Q_{\text{left}}(k_2) &= -C_1 \frac{\phi}{2\pi/L_2}. \end{aligned} \quad (38)$$

Here $\Delta Q_{\text{right}}(k_2)$ and $\Delta Q_{\text{left}}(k_2)$ are the edge state occupation (or change of polarization³⁸) of the adiabatically evolved ($k_2 \rightarrow k_2 + \phi$) 1D system minus that of the original (k_2) system. In Fig. 5 we show the energy spectrum of the 2D Hall insulator with open boundary condition in the x_1 direction. A vertical cut of this spectrum at fixed k_2 yields the energy spectrum of the 1D model associated with parameter k_2 . In particular, the vertical cut at $k_2 = 0$ gives the energy spectrum of the QBT model under open boundary condition. Clearly the QBT model possesses zero energy edge states. From the degeneracy and wavefunctions of the $E = 0$ eigenstates we deduce that there is one edge state localized at each end of the system. According to Fig. 5 in addition to $k_2 = 0$, the $k_2 = \pi$ system also possesses zero energy edge states. This is not so surprising because $k_2 = 0 \rightarrow k_2 = \pi$ corresponds to reversing the sign of δt in the QBT model. By calculating the eigenfunctions associated with the in-gap band we find that the upward ($dE(k_2)/dk_2 > 0$) dispersing branches near both $k_2 = 0$ and π are associated with the right edge, while the downward dispersing ones are associated with the left edge. This is also not surprising because a $C_1 = 2$ Hall insulator should have two co-moving chiral edge branches at each edge.

In Fig. 6 we zoom in on the in-gap band of Fig. 5. Here the blue and red dots represent occupied and empty k_2 ($= 2\pi n/L_2$) states respectively. Panel (a) is the occupation before the adiabatic evolution and panel (b) is that after the adiabatic evolution. For the upward dispersing branch $k_2 \rightarrow k_2 + \phi$ induces an extra number ($= \frac{\phi}{2\pi/L_2}$) of occupied k_2 values near each Dirac point ($k_2 = 0, \pi$). Similarly, for the downward dispersing branch there are exactly the same number of extra empty k_2 values. As a result, the C_1 in Eq. (38) counts the number of Dirac points in Fig. 5. Equivalently it counts the number of times the edge states cross Fermi energy ($E = 0$) as the parameter k_2 of the 1D Hamiltonian sweeps from 0 to 2π . (Note that a crossing from below $E = 0$ to above is counted as +1 while the reverse is counted as -1.) Of course, the fact that when a parameter of a 1D system is varied, charges flow from one end of the system to the other is the charge pumping effect^{18,39}.

FIG. 5: (color on-line) The energy spectrum of the 2D Hall insulator with open boundaries in the x_1 direction. Vertical cut of this spectrum at fixed k_2 yields the energy spectrum of the 1D model associated with parameter k_2 . The vertical cut at $k_2 = 0$ gives the energy spectrum of the open-boundary QBT model.

FIG. 6: (color on-line) (a) The occupation of the edge states. Blue dots represent occupied states and the red dots mark the unoccupied states. (b) The occupation after the adiabatic change $k_2 \rightarrow k_2 + \phi$.

D. The WZW term in $d = 0$

This time we start from the 2D Hall insulator on a torus, and insert fluxes $L_1\theta_1(t)$ and $L_2\theta_2(t)$ through both holes and fix the gauge so that $A_0 = 0$, $A_1 \rightarrow \theta_1(t)$, and $A_2 \rightarrow \theta_2(t)$. Substitute these changes into the Chern-Simons action (Eq. (26)) we obtain

$$S_{CS_1} \rightarrow S_{CS_1} = \frac{iC_1}{4\pi} L_1 L_2 \int dt \epsilon^{ab} \theta_a(t) \partial_0 \theta_b(t), \quad (39)$$

where $a, b = 1, 2$. Now let us introduce an auxiliary coordinate $u \in [0, 1]$ so that $\theta_{1,2}(t, u)$ smoothly interpolate between $\theta_{1,2}(t, u = 0) = 0$, and $\theta_{1,2}(t, u = 1) = \theta_{1,2}(t)$.

FIG. 7: (color on-line) (a) The map $(k_1, k_2) \rightarrow \hat{n}(k_1, k_2)$, where $k_{1,2} \in [0, 2\pi)$.

Then, Eq. (26) can be rewritten as

$$\begin{aligned}
 S_{CS_1} &= -\frac{iC_1}{4\pi} L_1 L_2 \int dt \int_0^1 du \epsilon^{uv} \epsilon^{ab} \partial_u (\theta_a(t, u) \partial_\nu \theta_b(t, u)), \\
 &= -\frac{iC_1}{4\pi} L_1 L_2 \int dt \int_0^1 du \epsilon^{\mu\nu} \epsilon^{ab} \partial_\mu (\theta_a(t, u) \partial_\nu \theta_b(t, u)), \\
 &= -\frac{iC_1}{4\pi} L_1 L_2 \int_0^1 du \int dt \epsilon^{\mu\nu} \epsilon^{ab} \partial_\mu \theta_a(t, u) \partial_\nu \theta_b(t, u),
 \end{aligned} \tag{40}$$

where $\mu = 0$ labels the time and $\mu = 1$ labels the u coordinate. In the derivation above, we employed the fact that the only boundary is in the u direction so that inte-

gral of a total derivative can be turned into a boundary integral along the u -direction.

Since θ_1 and θ_2 do not depend on the spatial coordinates x_1 and x_2 , k_1 and k_2 remain as good quantum numbers. Thus Eq. (39) should be the sum of the Berry's phase generated by $L_1 L_2$ number of zero-dimensional systems. Each of this system is parameterized by k_1 and k_2 and is governed by the following time-dependent Hamiltonian

$$H(t; k_{1,2}) = \vec{B}(t, k_{1,2}) \cdot \vec{\tau}, \tag{41}$$

where the “effective” magnetic field $\vec{B}(t, k_{1,2})$ is given by

$$\begin{aligned}
 B_x(t, k_{1,2}) &= 1 - m^2 \cos^2(k_2 + \theta_2(t)) \\
 &\quad + [1 + m^2 \cos^2(k_2 + \theta_2(t))] \cos(k_1 + \theta_1(t)), \\
 B_y(t, k_{1,2}) &= -2m \sin(k_1 + \theta_1(t)) \cos(k_2 + \theta_2(t)), \\
 B_z(t, k_{1,2}) &= 2m \sin(k_2 + \theta_2(t)).
 \end{aligned} \tag{42}$$

The three components of the effective magnetic field are just the three masses of the zero-dimensional systems labeled by $k_{1,2}$. The sum of the Berry's phase $S_B[k_1 + \theta_1(t), k_2 + \theta_2(t)]$ associated with each $H(t; k_{1,2})$ is equal to S_{CS_1} , namely

$$S_{CS_1} = \sum_{k_1, k_2} S_B[k_1 + \theta_1(t), k_2 + \theta_2(t)]. \tag{43}$$

Because the following identity which computes the first Chern number⁴⁰ C_1 as well as the Pontryagin index P of the map $(k_1, k_2) \rightarrow \hat{n} \equiv \vec{B}(\theta_{1,2}(t, u) + k_{1,2}) / |\vec{B}(\theta_{1,2}(t, u) + k_{1,2})|$

$$C_1 = P = \frac{1}{4\pi} \int d^2 k \epsilon^{abc} n_a(k_{1,2} + \theta_{1,2}(t, u)) \frac{\partial}{\partial k_1} n_b(k_{1,2} + \theta_{1,2}(t, u)) \frac{\partial}{\partial k_2} n_c(k_{1,2} + \theta_{1,2}(t, u)), \tag{44}$$

is true regardless of the values of $\theta_1(t, u)$ and $\theta_2(t, u)$ (see Fig. 7), we will show that $S_B[k_1 + \theta_1(t, u), k_2 + \theta_2(t, u)]$ is a WZW term of a spin-1/2 system. To do so, we rewrite S_{CS_1} as follows:

$$\begin{aligned}
 S_{CS_1} &= -\frac{iC_1}{4\pi} L_1 L_2 \int dt \int_0^1 du \epsilon^{\mu\nu} \epsilon^{\alpha\beta} \partial_\mu \theta_\alpha(t, u) \partial_\nu \theta_\beta(t, u), \\
 &= -i \frac{C_1/P}{16\pi^2} L_1 L_2 \int dt \int_0^1 du \int d^2 k \epsilon^{\mu\nu} \epsilon^{\alpha\beta} [\partial_\mu \theta_\alpha(t, u) \partial_\nu \theta_\beta(t, u)] \\
 &\quad \times [\epsilon^{abc} n_a(k_{1,2} + \theta_{1,2}(t, u)) \partial_{k_1} n_b(k_{1,2} + \theta_{1,2}(t, u)) \partial_{k_2} n_c(k_{1,2} + \theta_{1,2}(t, u))],
 \end{aligned} \tag{45}$$

$$\begin{aligned}
 &= -i \frac{C_1/P}{16\pi^2} L_1 L_2 \int dt \int_0^1 du \int d^2 k \epsilon^{\mu\nu} \epsilon^{\alpha\beta} [\partial_\mu \theta_\alpha(t, u) \partial_\nu \theta_\beta(t, u)] \\
 &\quad \times [\epsilon^{abc} n_a(k_{1,2} + \theta_{1,2}(t, u)) \partial_{\theta_1} n_b(k_{1,2} + \theta_{1,2}(t, u)) \partial_{\theta_2} n_c(k_{1,2} + \theta_{1,2}(t, u))],
 \end{aligned} \tag{46}$$

$$= \sum_{k_1, k_2} \left[-i \frac{C_1/P}{2} \int dt \int_0^1 du \epsilon^{abc} n_a(k_{1,2} + \theta_{1,2}(t, u)) \partial_t n_b(k_{1,2} + \theta_{1,2}(t, u)) \partial_u n_c(k_{1,2} + \theta_{1,2}(t, u)) \right], \tag{47}$$

where we employed the chain rule of differentiation from Eq. (46) to Eq. (47). Because all zero-dimensional subsystems can be adiabatically connected without closing the gap, each of them is then characterized by the same WZW term with the same level. Since $S_{CS_1} = \sum_{k_1, k_2} S_B[k_1 + \theta_1(t), k_2 + \theta_2(t)]$ and $C_1/P = 1$, we conclude that

$$S_B[\hat{n}(t)] = -i \frac{1}{2} \int dt \int_0^1 du \epsilon^{abc} n_a \partial_t n_b \partial_u n_c, \quad (48)$$

which is nothing but the well-known Berry phase or WZW term describing a spin-1/2 in a time-dependent magnetic field, as expected!

E. The θ term in $d = 0$

The last subsection establishes the fact that the Berry phase (WZW term) associated with the Hamiltonian $H(t) = \hat{n}(t) \cdot \vec{\tau}$ is

$$S_B = -\frac{i}{2} \int dt \int_0^1 du \epsilon^{abc} n_a \partial_t n_b \partial_u n_c, \quad (49)$$

where $\hat{n}(t, 0) = (1, 0, 0)$ and $\hat{n}(t, 1) = \hat{n}(t)$. Physically S_B measures half of the solid angle sustained by $\hat{n}(t, u)$ at $u = 1$ (i.e. the physical $\hat{n}$ trajectory) and the north pole ($\hat{n}(t, u = 0)$). For the case where

$$\hat{n}(t, u = 1) = (\sin \theta_0 \cos \phi(t), \sin \theta_0 \sin \phi(t), \cos \theta_0) \quad (50)$$

Eq. (49) becomes

$$S_B \rightarrow -i \left(\frac{1 - \cos \theta_0}{2} \right) \int dt \frac{d\phi}{dt}. \quad (51)$$

This is the θ -term.

The above is a simple example ($n = 1$) of the correspondence between a $2n$ -dimensional Chern-Simons insulator and $(n - 1)$ -dimensional topological NL σ models. This serves as a warm up exercise for the following discussions of the correspondence between a 4D ($n = 2$) Chern-Simons insulator and NL σ models in 1D.

V. A 4D CHERN-SIMONS INSULATOR AND THE CORRESPONDING 1D TOPOLOGICAL NL σ MODELS

In a one dimensional chain (whose gapless excitations near the right and left Fermi points are described by a massless Dirac theory) the dimerization and the antiferromagnetic Neel order parameter form a four vector. The quantum NL σ model describing this “super-vector” possesses a topological, WZW, term²⁷. Among others, this means the defects of one order carry the quantum number of the other order. Indeed, in the presence of spin the dimerization domain wall has two (one for each

spin species) zero modes. Among the four ways of occupying them, two lead to charge-neutral spin 1/2 solitons, and the other two lead to charge ± 1 spin zero solitons. The condensation of the former (which is favored by repulsive interactions) leads to the (algebraic) antiferromagnetic order and the condensation of the latter (which is favored by attractive interactions) leads to (algebraic) charge density wave/superconducting order. The former scenario is encapsulated by the dimerization-antiferromagnetic WZW term discussed above.

In the presence of spin, the QBT model described in section I, has four zero modes per dimerization domain wall (two for each spin). There are totally 16 possible ways to occupy them. Two give rise to charge ± 2 spin zero, eight lead to charge ± 1 spin 1/2, three give charge 0 spin 1, and another three give charge 0 spin 0 solitons. Therefore in this case the destruction of the dimerization order by condensation of domain walls can lead to a large number of possible states. In this section we will focus on the condensation of spin-1 charge neutral solitons. This should lead to spin-1 antiferromagnetic state which has a Haldane gap. The purpose of the following subsections is to study the WZW term associated with the transition between the dimerized phase and the Haldane phase. In addition, we shall also discuss the edge states of the spin-1 chain, the θ term and their relation to the physics of 3D TBIs.

A. The QBT model and a 4D Chern-Simons insulator

In the following we shall find that the $d = 1$ topological NL σ models discussed above is related to a Chern-Simons (or quantum Hall) insulator in $d = 4$ dimensions, which is constructed in Ref. [41]. This is the $n = 2$ example of the correspondence discussed in the introductory section. The Hamiltonian for the 4D Chern-Simons insulator is defined as follow:

$$H(k_1, k_2, k_3, k_4) = -[(1 - m_4^2) + (1 + m_4^2) \cos(k_4)] \Gamma_5 - m_1 \Gamma_1 - m_2 \Gamma_2 - m_3 \Gamma_3 - 2m_4 \sin(k_4) \Gamma_4, \quad (52)$$

where

$$\begin{aligned} m_1 &= \sin k_1, \\ m_2 &= \sin k_2, \\ m_3 &= \sin k_3, \\ m_4 &= m + \cos k_1 + \cos k_2 + \cos k_3, \end{aligned} \quad (53)$$

and

$$\Gamma_{1,2,3} = \tau_1 \otimes \sigma_{1,2,3}, \quad \Gamma_4 = \tau_2 \otimes I, \quad \Gamma_5 = \tau_3 \otimes I \quad (54)$$

Here I is 2×2 the identity matrix. The Pauli matrices τ and σ have sublattices (orbitals) and spin degrees of freedom respectively. By setting $k_{1,2,3}$ to zero one can see

that the Hamiltonian in Eq. (52) and Eq. (53) reduces to the spinful version of Eq. (13), after a 90° rotation around the τ_2 axis. For, e.g., $m = -2.5$, straightforward computation shows that the above Hamiltonian has a non-zero second Chern number (also see Ref. 18), $C_2 = 2$, where

$$C_2 = \frac{1}{4\pi^2} \int d^4k \text{Tr} [f_{12}f_{34} - f_{13}f_{24} + f_{14}f_{23}] \quad (55)$$

with the momentum space Berry curvature given by

$$f_{\mu\nu}(\mathbf{k}) = \frac{-i}{(E_G(\mathbf{k}) - E_E(\mathbf{k}))^2} \quad (56)$$

$$\times (P_G(\mathbf{k}) \cdot \partial_{k_\mu} H(\mathbf{k}) \cdot P_E(\mathbf{k}) \cdot \partial_{k_\nu} H(\mathbf{k}) \cdot P_G(\mathbf{k}) - \mu \leftrightarrow \nu).$$

Here we note that because the Hamiltonian is constructed out of Γ matrices, its eigenvalues have the form $(-E, -E, +E, +E)$. In Eq. (57) E_G is the energy of the two occupied levels and E_E is that of two unoccupied levels, and the projection operators P_G, P_E are defined as follows

$$P_G(\mathbf{k}) = \sum_{\alpha=\text{occupied}} |u_{\alpha\mathbf{k}}\rangle \langle u_{\alpha\mathbf{k}}|$$

$$P_E(\mathbf{k}) = \sum_{\beta=\text{empty}} |u_{\beta\mathbf{k}}\rangle \langle u_{\beta\mathbf{k}}|. \quad (57)$$

After integrating out the fermions, the effective gauge action associated with such a Chern-Simons insulator is¹⁸

$$S_{CS_2} = -i \frac{C_2}{24\pi^2} \int dt d^4x \epsilon^{\mu\nu\lambda\rho\sigma} A_\mu \partial_\nu A_\lambda \partial_\rho A_\sigma. \quad (58)$$

Eq. (52) and Eq. (58) play the roles of Eq. (25) and Eq. (26) in the following discussions.

B. The existence of surface states in 3D TBIs

We start with the Chern-Simons insulator described by Eq. (52) and Eq. (53) on a real-space 4-dimensional lattice with periodic boundary conditions (hence form a 4D torus). Let us insert flux $L_4\phi$ in the fourth hole (hence $A_4 \rightarrow \phi$) and restrict $A_{0,1,2,3}$ to depends on only t and $x_{1,2,3}$. Under this condition Eq. (58) becomes

$$S_{\text{eff}} = -i \frac{C_2\phi}{8\pi^2} L_4 \int d^3x dt \epsilon^{\nu\lambda\rho\sigma} \partial_\nu A_\lambda \partial_\rho A_\sigma. \quad (59)$$

Since the translation symmetry in x_4 remains, k_4 is a good quantum number. Thus the above effective action is the sum of the Berry phase action of an assembly of 3D systems, each labeled by a different k_4 :

$$\sum_{k_4} S_{3D} [k_4 + \phi; A_\mu]$$

$$= -i \frac{C_2\phi}{8\pi^2} L_4 \int d^3x dt \epsilon^{\nu\lambda\rho\sigma} \partial_\nu A_\lambda \partial_\rho A_\sigma \quad (60)$$

Subtract the $\phi = 0$ version of Eq. (60) from the above result, we obtain

$$\sum_{k_4} (S_{3D} [k_4 + \phi; A_\mu] - S_{3D} [k_4; A_\mu])$$

$$= -i \frac{C_2\phi}{8\pi^2} L_4 \int d^3x dt \epsilon^{\nu\lambda\rho\sigma} \partial_\nu A_\lambda \partial_\rho A_\sigma. \quad (61)$$

For non-compact gauge field, since the integrand of the right hand side is a pure derivative, it is only nonzero in the presence of boundary. With spatial boundaries

$$-i \frac{C_2\phi}{8\pi^2} L_4 \int d^3x dt \epsilon^{\nu\lambda\rho\sigma} \partial_\nu A_\lambda \partial_\rho A_\sigma$$

$$= -i \frac{C_2\phi}{8\pi^2} L_4 \oint d^2x dt n_\nu [\epsilon^{\nu\lambda\rho\sigma} A_\lambda \partial_\rho A_\sigma] \quad (62)$$

where n_ν is the ν th component of the unit surface normal. Note that the right hand side of the above expression is the first Chern-Simons action defined on the surface suggesting surface Hall effect as discussed in Ref. [18]. Combining Eq. (61) and Eq. (62) we conclude

$$\sum_{k_4} \Delta\sigma_{xy, \text{ surface}}(k_4) = \frac{C_2}{2\pi} \frac{L_4\phi}{2\pi}. \quad (63)$$

Here $\Delta\sigma_{xy, \text{ surface}}(k_4)$ is the difference in the surface Hall conductance between the adiabatically evolved ($k_4 \rightarrow k_4 + \phi$) system and the original (k_4) system. Eq. (63) is in close analogy of Eq. (38) in earlier discussions.

Since for two dimensional Dirac electrons a change of mass from negative to positive induces $\Delta\sigma_{xy} = 1/2\pi$, the above result strongly suggests that as $k_4 \rightarrow k_4 + \phi$, C_2 number of massless surface Dirac Hamiltonians are encountered. Let us label the k_4 values at which the surface Dirac Hamiltonian is massless by k_4^* s. As these special k_4^* s are crossed under $k_4 \rightarrow k_4 + \phi$, the mass of the surface Hamiltonians change sign. Eq. (63) requires when we compare the masses of the adiabatic evolved surface Hamiltonians with the original ones we will find $C_2 \times L_4\phi/2\pi$ mass reversals.

For the model discussed in Eq. (52) this is indeed true. Under the condition x_3 direction is open, while $x_{1,2}$ directions have periodic boundary conditions, the surface Hamiltonians read

$$H_{\text{surf}}(\mathbf{k})$$

$$= \begin{cases} v(-k_1\sigma_2 + k_2\sigma_1) + m(k_4)\sigma_3 & \text{top surface} \\ v(k_1\sigma_2 + k_2\sigma_1) + m(k_4)\sigma_3 & \text{bottom surface} \end{cases} \quad (64)$$

where v is a velocity parameter, $k_{1,2}$ are the components of the surface wavevector. The mass term $m(k_4)$ vanishes when $k_4 = k_4^*$. Surprisingly, despite the fact that the Hamiltonian in Eq. (52) is time-reversal invariant, the k_4^* s are not 0 or π . Instead, we find a pair of $k_{4,1}^*$ and $k_{4,2}^* = 2\pi - k_{4,1}^*$ where $m(k_4)$ vanishes. The value of these two k_4^* s value depend on the parameter m in Eq. (53).

FIG. 8: (color on-line) The circle represents $k_4 \in [0, 2\pi)$ and the red points mark $k_{4,1}^*$ and $k_{4,2}^*$. The green arcs in the vicinity of $k_4 = 0$ and $k_4 = \pi$ mark the regime in k_4 where the surface bands merge into the bulk continuum. In these k_4 intervals the surface states on the top and bottom surfaces re-hybridize, and the surface Hall conductance vanishes.

For example for $m = -2.5$ we find $k_{4,1}^* = 0.6992282\pi$ and $k_{4,2}^* = 2\pi - 0.6992282\pi$. In Fig. 9 we show the k_4 -dependence of the energy spectrum of H in Eq. (52) under open boundary condition in x_3 , and with (k_1, k_2) fixed at $(0, 0)$. In addition to the gapless points $k_{4,1}^*$ and $k_{4,2}^*$ there is another important feature worthy of attention. In the vicinity of $k_4 = 0$ and $k_4 = \pi$ (marked by green) the surface bands merge into the bulk continuum. As a result, the surface states on the top and bottom surfaces re-hybridize, resulting in the vanishing of the surface Hall conductance. This is illustrated in Fig. 8 where the circle represents $k_4 \in [0, 2\pi)$ and the red points mark $k_{4,1}^*$ and $k_{4,2}^*$. The green arcs represent the intervals of k_4 in which the surface bands merge into the bulk continuum. It is important to note that there is no gap closing at either ends of these arcs.

In Fig. 10, we plot the energy spectrum associated with $k_{4,1}^*$ as a function of $k_{1,2}$. Note that despite the fact that for $k_4 \neq 0$ or π time-reversal is broken, the surface Dirac point is located at $\mathbf{k} = (0, 0)$. In addition, at $k_4 = k_{4,1}^*$ and $k_{4,2}^*$ the low energy surface Hamiltonians are completely time-reversal invariant! The fact there exists two k_4^* s at which $k_4 \rightarrow k_4 + \phi$ induces $m(k_4)$ to change from negative to positive, is consistent with the fact that $C_2 = 2$ in Eq. (63). Because of the k_4^* s are not time reversal invariant, there is no time reversal symmetry that protects the gapless Dirac surface states. However, finding symmetry protected gapless Dirac surface states is not the purpose of this paper.

C. The WZW action in 1+1 D

The purpose of this section is to derive the $NL\sigma$ model describing the competing dimerization and magnetic or-

FIG. 9: (color on-line) The spectrum of Eq. (52) at surface momenta $k_1 = k_2 = 0$ as a function of k_4 . The two points at which the surface bandgap closes are $k_{4,1}^*$ and $k_{4,2}^*$.

FIG. 10: (color on-line) The surface band structure obtained by setting k_4 in Eq. (52) to one of the special values (marked by the red dots) in Fig. 8.

der described at the beginning of section IV.

We start with the 4D topological insulator described by Eq. (52) and Eq. (53) and insert magnetic fluxes $L_{1,2,3}\theta_{1,2,3}$ in the first to the third holes of the 4D torus. Moreover, we shall restrict $\theta_{1,2,3}$ to depend only on x_4 and t . By substituting $A_{1,2,3} \rightarrow \theta_{1,2,3}(x_4, t)$ and fix the gauge so that $A_{0,4} \rightarrow 0$, Eq. (58) becomes

$$S_{CS_2} \rightarrow -i \frac{C_2}{12\pi^2} L_1 L_2 L_3 \int dt dx_4 \epsilon^{abc} \theta_a \partial_0 \theta_b \partial_4 \theta_c, \quad (65)$$

where $a, b, c = 1, 2, 3$. Since $k_{1,2,3}$ are good quantum numbers, Eq. (65) is the sum of the Berry phase action of an assembly of one dimensional systems, each parameterized by (k_1, k_2, k_3) , i.e.,

$$\begin{aligned} & \sum_{k_1, k_2, k_3} S_{1D}[k_{1,2,3} + \theta_{1,2,3}] \\ &= -i \frac{C_2}{12\pi^2} L_1 L_2 L_3 \int dt dx_4 \epsilon^{abc} \theta_a \partial_0 \theta_b \partial_4 \theta_c \end{aligned} \quad (66)$$

Again, we introduce an auxiliary coordinate $u \in [0, 1]$ so that $\theta_{1,2,3}(t, u)$ smoothly interpolate between $\theta_{1,2,3}(t, u = 0) = 0$ and $\theta_{1,2,3}(t, u = 1) = \theta_{1,2,3}(t)$, and consider the following action

$$\begin{aligned} & -i \frac{C_2}{24\pi^2} \prod_{i=1}^3 L_i \int dt dx_4 \int_0^1 du \epsilon^{abc} \epsilon^{\mu\nu\lambda} \partial_\mu (\theta_a \partial_\nu \theta_b \partial_\lambda \theta_c) \\ & = -i \frac{C_2}{24\pi^2} \prod_{i=1}^3 L_i \int dt dx_4 \int_0^1 du \epsilon^{abc} \epsilon^{\mu\nu\lambda} \partial_\mu \theta_a \partial_\nu \theta_b \partial_\lambda \theta_c, \end{aligned} \quad (67)$$

where $\mu = 0, 1, 2$ labels the t, x_4 and u coordinates, respectively. Because the integrand of Eq. (67) is a total derivative it is equal to a boundary integral. Since boundaries only exist in the u direction we can easily show that Eq. (67) reduces to Eq. (65). As the result Eq. (66) implies

$$\begin{aligned} & \int \frac{dk_1 dk_2 dk_3}{(2\pi)^3} S_{1D}[k_{1,2,3} + \theta_{1,2,3}] \\ & = -i \frac{C_2}{24\pi^2} \int dt dx_4 \int_0^1 du \epsilon^{abc} \epsilon^{\mu\nu\lambda} \partial_\mu \theta_a \partial_\nu \theta_b \partial_\lambda \theta_c \end{aligned} \quad (68)$$

If we use j to label the lattice sites in the x_4 direction, the 1D Hamiltonian parameterized by $k_{1,2,3}$ is given by

$$\begin{aligned} H & = - \sum_j \psi_j^\dagger \left[(1 - m_4^2) \Gamma_5 + \sum_{\alpha=1}^3 m_\alpha \Gamma_\alpha \right] \psi_j \\ & - \sum_j \left[\psi_{j+1}^\dagger \left[\frac{1 + m_4^2}{2} \Gamma_5 - i m_4 \Gamma_4 \right] \psi_j + h.c. \right], \end{aligned} \quad (69)$$

where $m_{1,2,3,4}$ are given by

$$\begin{aligned} m_1 & = \sin(k_1 + \theta_1), \\ m_2 & = \sin(k_2 + \theta_2), \\ m_3 & = \sin(k_3 + \theta_3), \\ m_4 & = (m + \cos(k_1 + \theta_1) + \cos(k_2 + \theta_2) + \cos(k_3 + \theta_3)). \end{aligned} \quad (70)$$

In the following we shall set the parameter m to -2.5 . For $m_{1,2,3,4} = 0$ the dispersion of the one dimensional Hamiltonian is shown in Fig. 1(c) where both bands are doubly degenerate. The question is what kind of Berry phase action for m_α 's will be generated upon integrating out the fermions. (Due to the quadratic touching between the conduction and valence bands, the gradient expansion method discussed in Ref.[30] no longer works.)

It can be checked that the following three-torus to S^3 mapping $(k_1, k_2, k_3) \rightarrow n_\alpha(k_{1,2,3} + \theta_{1,2,3}) \equiv m_\alpha(k_{1,2,3} + \theta_{1,2,3}) / \sqrt{\sum_{\alpha=1}^4 m_\alpha^2(k_{1,2,3} + \theta_{1,2,3})}$ has Pontryagin index $P = 1$ regardless of the $\theta_{1,2,3}$ values, where

$$P = \frac{1}{2\pi^2} \int_0^{2\pi} \prod_{\alpha=1}^3 dk_\alpha \epsilon^{abcd} n_a \partial_{k_1} n_b \partial_{k_2} n_c \partial_{k_3} n_d. \quad (71)$$

Given this fact and Eq. (67), we now show that the desired Berry phase action generated by integrating out the fermion is the WZW action

$$\begin{aligned} & S_{WZW}[\hat{n}(x_4, t)] \\ & = -\frac{iC_2}{6\pi} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{abcd} n_a \partial_\mu n_b \partial_\nu n_c \partial_\lambda n_d. \end{aligned} \quad (72)$$

The proof is similar to what we did earlier in section III, namely, just using chain rule of differentiation. If integrating out fermion indeed generate Eq. (72), consistency with Eq. (68) would require

$$\begin{aligned} & -\frac{iC_2}{6\pi} \int \prod_{i=1}^3 \frac{dk_i}{2\pi} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{abcd} n_a \partial_\mu n_b \partial_\nu n_c \partial_\lambda n_d \\ & = -i \frac{C_2}{24\pi^2} \int dt dx_4 \int_0^1 du \epsilon^{abc} \epsilon^{\mu\nu\lambda} \partial_\mu \theta_a \partial_\nu \theta_b \partial_\lambda \theta_c. \end{aligned} \quad (73)$$

Since each of the n_α depends on $k_{1,2,3} + \theta_{1,2,3}(t, x_4, u)$ we apply chain rule to the left hand side of Eq. (73):

$$\begin{aligned} & -\frac{iC_2}{6\pi} \int \frac{dk_1 dk_2 dk_3}{(2\pi)^3} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{abcd} n_a \partial_\mu n_b \partial_\nu n_c \partial_\lambda n_d \\ & = -\frac{iC_2}{6\pi} \int \frac{dk_1 dk_2 dk_3}{(2\pi)^3} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{abcd} n_a \partial_{\theta_\alpha} n_b \partial_{\theta_\beta} n_c \partial_{\theta_\gamma} n_d (\partial_\nu \theta_\alpha \partial_\nu \theta_\beta \partial_\lambda \theta_\gamma) \\ & = -\frac{iC_2}{6\pi} \int \frac{dk_1 dk_2 dk_3}{(2\pi)^3} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{abcd} n_a \partial_{\theta_1} n_b \partial_{\theta_2} n_c \partial_{\theta_3} n_d \epsilon^{\alpha\beta\gamma} (\partial_\nu \theta_\alpha \partial_\nu \theta_\beta \partial_\lambda \theta_\gamma) \\ & = -\frac{iC_2}{48\pi^4} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{\alpha\beta\gamma} \left(\int dk_1 dk_2 dk_3 \epsilon^{abcd} n_a \partial_{k_1} n_b \partial_{k_2} n_c \partial_{k_3} n_d \right) (\partial_\nu \theta_\alpha \partial_\nu \theta_\beta \partial_\lambda \theta_\gamma) \\ & = -\frac{iC_2}{24\pi^2} \int_0^1 du \int dx_4 dt \epsilon^{\mu\nu\lambda} \epsilon^{\alpha\beta\gamma} (\partial_\nu \theta_\alpha \partial_\nu \theta_\beta \partial_\lambda \theta_\gamma). \end{aligned} \quad (74)$$

Indeed, it agrees with the right hand side of Eq. (73)!

The non-linear σ model with the $C_2 = 2$ WZW term

$$S = \int dx_4 dt \partial_\mu n_\alpha \partial_\mu n_\alpha + S_{WZW}[n_\alpha(x_4, t)] \quad (75)$$

describes the critical point between the dimerised phase ($\langle m_0 \rangle \neq 0$) and the Haldane phase. This critical theory is realized in the spin-1 chain with quadratic and bi-quadratic exchanges:

$$H = J \sum_i [\mathbf{S}_i \cdot \mathbf{S}_{i+1} - (\mathbf{S}_i \cdot \mathbf{S}_{i+1})^2]. \quad (76)$$

It has been exactly solved by Takhtajan⁴² and Babujan⁴³, and the critical theory is that of level-2 $SU(2)$ WZW model whose NL σ model form is given by Eq. (75).

D. The $S = 1$ spin chain, edge states, and the θ term in the NL σ model

In this section we set $m_{1,2,3} \rightarrow \cos \theta_0 \hat{m}_{1,2,3}$ and $m_4 \rightarrow \sin \theta_0$. We consider the following fermion σ model

$$H = - \sum_j \psi_j^\dagger \left[(1 - \sin^2 \theta_0) \Gamma_5 + \cos \theta_0 \sum_{k=1}^3 \hat{m}_k \Gamma_k \right] \psi_j - \sum_j \left[\psi_{j+1}^\dagger \left[\frac{1 + \sin^2 \theta_0}{2} \Gamma_5 - i \sin \theta_0 \Gamma_4 \right] \psi_j + h.c. \right], \quad (77)$$

where the dimerization order parameter has been set to $\sin \theta_0$ and the magnetic order parameters to $\cos \theta_0 \hat{m}$. In the absence of the m_k 's Eq. (77) describes a one-dimensional TBI whose bandstructure is shown in Fig.2(a) (each band is now two-fold degenerate). Under the open boundary condition there is a doubly degenerate zero-energy edge states at each end of the chain. Using the representation

$$\Gamma_{1,2,3} = \tau_1 \otimes \sigma_{1,2,3}, \quad \Gamma_4 = \tau_2 \otimes I, \quad \Gamma_5 = \tau_3 \otimes I, \quad (78)$$

the edge states can be made eigenstates of τ_1 and σ_3 . The wavefunctions of these edge states are shown in Fig. 11. Notice that we have plotted $(-1)^n \psi_n$ (n is the site index) rather than simply ψ_n . This is because the minimum gap occurs at $k = \pi$ hence the these wavefunctions have a fast spatial modulation. In the presence of non-zero $\hat{m} = (\hat{m}_1, \hat{m}_2, \hat{m}_3)$ the degenerate edge states are split. The occupied state has magnetization along the local $\hat{m}$ direction. In the presence of space-time dependent $\hat{m}$, integrating out the fermions produces space-time dependent edge magnetic moments each contributing a Berry phase of the form given by Eq. (48). This is precisely the well-known spin-1/2 at the ends of the spin-1 chain.

FIG. 11: (color on-line) The envelope of the edge wavefunctions.

By letting $\hat{n}$ in Eq. (72) smoothly interpolate between $\hat{n}(t, x_4, u = 1) = (0, 0, 0, 1)$ and $\hat{n}(t, x_4, u = 0) = (\sin \theta_0, \cos \theta_0 \hat{m}(x_4, t))$ we obtain the θ -action for gapped spin chain

$$S_\theta = -i\theta \left[\frac{1}{4\pi} \int dx_4 dt \hat{m} \cdot \partial_t \hat{m} \times \partial_{x_4} \hat{m} \right], \quad (79)$$

where $\theta = C_2[\pi - \sin(2\theta_0) - 2\theta_0]$. When the system has some sort of discrete symmetry, such as inversion, which requires $m_4 = 0$ or $\theta_0 = 0$, the coefficient $\theta = C_2\pi$. If C_2 is an odd integer, the corresponding NL- σ model is gapless; if C_2 is an even integer, the NL σ model is gapped. When there is no such discrete symmetry, the bare coefficient of the θ term, in general, deviates from odd integral multiple of π , at low energy it renormalizes to the closest fixed point characterized by the θ term coefficient $2n\pi$, which corresponds to a gapped system. In our particular case the relevant value is 2π . This is in analogy with the Z_2 classification of 3D TBIs and the discrete symmetry, such as inversion, which protect the gapless modes for $\theta = (2n + 1)\pi$, plays the role of time reversal symmetry in 3D TBIs.

VI. SUMMARY

In this paper we have tackled the issue of what is the relation between the following two areas of topological condensed matter physics: topological band insulators and topological non-linear σ (NL σ) models. We have established a correspondence between a $2n$ -dimensional Chern-Simons band insulators and the $(n - 1)$ -dimensional NL σ models with the Wess-Zumino-Witten (WZW) term. The correspondence does not depend on whether in the absence of the order parameter (the σ fields) the original gapless $n - 1$ dimensional fermion Hamiltonian is Dirac-like or not. We have ap-

plied this correspondence to a simple 1D model where the gapless Hamiltonian exhibits a quadratic band touching. In the presence of the dimerization and antiferromagnetic order parameters, the fermion integration yields an $O(4)$ non-linear σ model whose WZW term has a doubled coefficient. This action describes the critical point between the dimerized phase and the Haldane phase. We demonstrate that the edge states of the $S = 1$ spin chain are nicely captured if one starts with the edge state of the dimerized 1D topological band insulator.

Appendix A: The proof of the correspondence between a $2n$ -dimensional Chern-Simons insulator and a $(n-1)$ -dimensional topological NL σ model

In this appendix we provide the proof of the Chern-Simons insulators $\leftrightarrow$ topological NL σ model correspondence discussed in the introduction.

We consider a $(n-1)$ -dimensional fermion- σ model described by the time-dependent Hamiltonian $H(\vec{k}; \vec{m}(t, \vec{x}))$, where $\vec{x} = (x_1, \dots, x_{n-1})$ and $\vec{k} = (k_1, \dots, k_{n-1})$ are the position and momentum in $(n-1)$ -dimensions, and $\vec{m}(t, \vec{x})$ is the space-time dependent $(n+2)$ -component order-parameter fields with a fixed $|\vec{m}(t, \vec{x})|$. We assume that the space and time derivatives of $\vec{m}(t, \vec{x})$ do not enter the Hamiltonian. When the order-parameter fields $\vec{m}(t, \vec{x})$ are set to zero, the corresponding Hamiltonian $H_0(\vec{k}) = H(\vec{k}; \vec{m}(t, \vec{x}) \rightarrow 0)$ is gapless. One familiar case is when $H_0(\vec{k})$ has linear dispersion at low energy. However, our following results apply for more general situations.

The condition we need to impose to $H_0(\vec{k})$ is that for constant m_a the Hamiltonian $H(\vec{k}; \vec{m})$ has a completely gapped spectrum, and for $0 < |\vec{m}| < m^*$ the energy gap does not close. The conditions we impose above apply for nearly all physically interesting situations. (Note that, in a continuum model where the linear Dirac dispersion extends to $E = \pm\infty$, m^* can be taken to ∞ since the energy gap never closes for any non-zero $|\vec{m}|$. This may not be true for lattice fermion models where the bandwidth of $H_0(\vec{k})$ is finite.) Physically m^* should be of the order of the band width of $H_0(\vec{k})$. For such $H(\vec{k}; \vec{m}(t, \vec{x}))$, we take the following steps to determine whether a WZW term will be generated by fermion integration.

Step 1, we create a $2n$ -dimensional Bloch Hamiltonian $H(\vec{k}; \lambda \vec{m}(\vec{p}))$, where $\vec{p} = (p_1, \dots, p_{n+1})$ and $(\vec{k}, \vec{p})$ is the $2n$ -component momentum, by simply replacing constant m_a in $H(\vec{k}; \vec{m})$ with $\lambda m_a(\vec{p})$. Most importantly we choose $\vec{m}(\vec{p})$ such that it has a nonzero Pontryagin index P (Eq. (8)). For instance, the following map

$$\begin{aligned} m_i(\vec{p}) &= \sin p_i, \text{ for } i = 1, \dots, n+1, \\ m_{n+2}(\vec{p}) &= (m - \sum_{i=1}^{n+1} \cos p_i) \end{aligned} \quad (\text{A1})$$

has the Pontryagin index (Eq. (8)) equal to one when the parameter m satisfies $n-1 < m < n+1$. Note that the parameter λ is introduced so that $|\lambda \vec{m}(\vec{p})| < m^*$. For such $|\lambda \vec{m}(\vec{p})|$, the Hamiltonian $H(\vec{k}; \lambda \vec{m}(\vec{p}))$ describes an insulator so that we can go step 2 below.

Step 2, we check whether the $2n$ -dimensional Bloch Hamiltonian $H(\vec{k}; \lambda \vec{m}(\vec{p}))$ possesses a non-zero n -th Chern number C_n (Eq. (9)). If $C_n \neq 0$, a level- $k = C_n/P$ WZW term (Eq. (4)) will be generated upon integrating out fermions in the $(n-1)$ -dimensional Hamiltonian $H(\vec{k}; \vec{m}(t, \vec{x}))$, so long as $|\vec{m}(t, \vec{x})| < m^*$. The following is the proof.

The electromagnetic gauge action of a $2n$ -dimensional Chern-Simons insulator contains the following topological term^{18,44}

$$S_{CS_n} = -i \frac{C_n}{(n+1)!(2\pi)^n} \int dt d^{2n}x \left[\epsilon^{a_1 \dots a_{2n+1}} A_{a_1} \partial_{a_2} A_{a_3} \dots \partial_{a_{2n}} A_{a_{2n+1}} \right], \quad (\text{A2})$$

where $a_i = 0, 1, \dots, 2n$ labels $t, x_1, \dots, x_{2n}$ respectively, ϵ is the $(2n+1)$ d antisymmetric tensor. Now, we choose

$$\begin{aligned} A_\mu(t, x_1, \dots, x_{2n}) &= 0, \text{ for } \mu = 0, \dots, n-1; \\ A_{i+n-1}(t, x_1, \dots, x_{2n}) &= \theta_i(t, x_1, \dots, x_{n-1}), \text{ for } i = 1, \dots, n+1. \end{aligned} \quad (\text{A3})$$

For this choice of gauge potential, the Chern-Simons action becomes

$$S_{CS_n} \rightarrow -i \frac{C_n}{(n+1)!(2\pi)^n} \left[\prod_{i=n}^{2n} L_i \right] \int dt d^{n-1}x \epsilon^{a_1 \cdots a_n} \epsilon^{b_1 \cdots b_{n+1}} \theta_{b_1} \partial_{a_1} \theta_{b_2} \cdots \partial_{a_n} \theta_{b_{n+1}} \quad (\text{A4})$$

where $a_i = 0, 1, \dots, n-1$ represents $t, x_1, \dots, x_{n-1}$ respectively, $b_i = 1, \dots, n+1$, and $d^{n-1}x \equiv dx_1 \cdots dx_{n-1}$. (Note that a overall n -dependent sign is ignored above and hereafter since it can be absorbed by relabeling the components of $\hat{n}$.) We introduce an auxiliary coordinate $u \in [0, 1]$ so that $\theta_i(t, \vec{x}, u)$ ($i = 1, \dots, n+1$) smoothly interpolate between $\theta_i(t, \vec{x}, u=0) = 0$ and $\theta_i(t, \vec{x}, u=1) = \theta_i(t, \vec{x})$. [$\vec{x} \equiv (x_1, \dots, x_{n-1})$]. In the following $a_i = 0, 1, \dots, n$ will correspond to $t, x_1, \dots, x_{n-1}, u$ respectively, and $\epsilon^{01 \cdots n} = 1$. Under this condition Eq. (A4) can be rewritten as

$$S_{CS_n} = -i \frac{C_n}{(n+1)!(2\pi)^n} \left[\prod_{i=n}^{2n} L_i \right] \int dt d^{n-1}x \int_0^1 du \epsilon^{a_1 \cdots a_n a_{n+1}} \epsilon^{b_1 \cdots b_{n+1}} \partial_{a_{n+1}} \left[\theta_{b_1} \partial_{a_1} \theta_{b_2} \cdots \partial_{a_n} \theta_{b_{n+1}} \right], \quad (\text{A5})$$

$$= -i \frac{C_n}{(n+1)!(2\pi)^n} \left[\prod_{i=n}^{2n} L_i \right] \int dt d^{n-1}x \int_0^1 du \epsilon^{a_1 \cdots a_n a_{n+1}} \epsilon^{b_1 \cdots b_{n+1}} \left[\partial_{a_{n+1}} \theta_{b_1} \partial_{a_1} \theta_{b_2} \cdots \partial_{a_n} \theta_{b_{n+1}} \right], \quad (\text{A6})$$

$$= -i \frac{C_n}{(n+1)!(2\pi)^n} \left[\prod_{i=n}^{2n} L_i \right] \int dt d^{n-1}x \int_0^1 du \epsilon^{a_1 \cdots a_n a_{n+1}} \epsilon^{b_1 \cdots b_{n+1}} \left[\partial_{a_1} \theta_{b_1} \partial_{a_2} \theta_{b_2} \cdots \partial_{a_{n+1}} \theta_{b_{n+1}} \right]. \quad (\text{A7})$$

In passing from Eq. (A4) to Eq. (A5), we have used the fact that the system is periodic in $t, x_1, \dots, x_{n-1}$ directions; the integral in Eq. (A5) is equal to Eq. (A4) because only the u -direction has boundaries.

Since the θ 's do not depend on the coordinates $(x_n, \dots, x_{2n})$, translation symmetry in these $(n+1)$ directions remain intact, and the associated momenta $\vec{p}$ are good quantum numbers. As a result the $2n$ -dimensional system decouples into $\left[\prod_{i=n}^{2n} L_i \right]$ number of $(n-1)$ -dimensional subsystems each labeled by a different $\vec{p}$, and is described by the Hamiltonian $\tilde{H}(\vec{k}; \vec{m}(\vec{p} + \vec{\theta}(t, \vec{x})))$. Let $S_{(n-1)D}(\vec{p})$ be the topological action of each of these $n-1$ dimensional systems (upon integrating out the fermions), they satisfy

$$\sum_{\vec{p}} S_{(n-1)D}(\vec{p}) = S_{CS_n}. \quad (\text{A8})$$

For a fixed $\vec{\theta}(t, \vec{x})$ profile, the Pontryagin index of the map $\vec{p} \rightarrow \hat{n}(\vec{p} + \vec{\theta}) \equiv \vec{m}(\vec{p} + \vec{\theta})/|\vec{m}(\vec{p} + \vec{\theta})|$ is given by

$$P = \frac{1}{\text{Area}(S^{n+1})} \int d^{n+1}\vec{p} \epsilon^{c_1 \cdots c_{n+2}} n_{c_1}(\vec{p} + \vec{\theta}) \partial_{p_1} n_{c_2}(\vec{p} + \vec{\theta}) \cdots \partial_{p_{n+1}} n_{c_{n+2}}(\vec{p} + \vec{\theta}), \quad (\text{A9})$$

$$= \frac{1}{\text{Area}(S^{n+1})} \int d^{n+1}\vec{p} \epsilon^{c_1 \cdots c_{n+2}} \left[n_{c_1}(\vec{p} + \vec{\theta}) \partial_{\theta_1} n_{c_2}(\vec{p} + \vec{\theta}) \cdots \partial_{\theta_{n+1}} n_{c_{n+2}}(\vec{p} + \vec{\theta}) \right] \Big|_{\vec{\theta} \rightarrow \vec{\theta}(t, \vec{x})}. \quad (\text{A10})$$

It is important to note that the Pontryagin index of $\vec{m}(\vec{p} + \vec{\theta})$ is independent on $\vec{\theta}$. Now, we can rewrite S_{CS_n} as follows:

$$S_{CS_n} = S_{CS_n} \cdot \left[\frac{1}{P} \frac{1}{\text{Area}(S^{n+1})} \int d^{n+1}\vec{p} \epsilon^{c_1 \cdots c_{n+2}} n_{c_1} \partial_{\theta_1} n_{c_2} \cdots \partial_{\theta_{n+1}} n_{c_{n+2}} \right] \quad (\text{A11})$$

$$= -i \frac{1}{(n+1)!(2\pi)^n} \frac{C_n/P}{\text{Area}(S^{n+1})} \left[\prod_{i=n}^{2n} L_i \right] \int d^{n+1}\vec{p} \int dt d^{n-1}\vec{x} \int_0^1 du \left[\epsilon^{c_1 \cdots c_{n+2}} n_{c_1} \partial_{\theta_1} n_{c_2} \cdots \partial_{\theta_{n+1}} n_{c_{n+2}} \right] \\ \times \left[\epsilon^{a_1 \cdots a_{n+1}} \epsilon^{b_1 \cdots b_{n+1}} \partial_{a_1} \theta_{b_1} \partial_{a_2} \theta_{b_2} \cdots \partial_{a_{n+1}} \theta_{b_{n+1}} \right], \quad (\text{A12})$$

$$= \sum_{\vec{p}} \left[-i \frac{C_n}{P} \frac{2\pi}{\text{Area}(S^{n+1})(n+1)!} \int dt d^{n-1}\vec{x} \int_0^1 du \epsilon^{c_1 \cdots c_{n+2}} \epsilon^{a_1 \cdots a_{n+1}} n_{c_1} \partial_{a_1} n_{c_2} \cdots \partial_{a_{n+1}} n_{c_{n+2}} \right], \quad (\text{A13})$$

In going from Eq. (A12) to Eq. (A13) we have applied the chain rule of differentiation. Note that because, for different $\vec{p}$, the Hamiltonians $H(\vec{k}; \lambda \vec{m}(\vec{p} + \vec{\theta}(t, \vec{x})))$ can be adiabatically deformed into one another without closing the energy gap, the subsystems correspond to different $\vec{p}$ should share the same form of WZW term with the same quantized

coefficient. Since $S_{CS_n} = \sum_{\vec{p}} S_{(n-1)D}(\vec{p})$, we conclude that

$$\begin{aligned} S_{(n-1)D}(\vec{p}) &= -i \frac{C_n}{P} \frac{2\pi}{\text{Area}(S^{n+1})(n+1)!} \int dt d^{n-1}x \int_0^1 du \epsilon^{c_1 \cdots c_{n+2}} \epsilon^{a_1 \cdots a_{n+1}} n_{c_1} \partial_{a_1} n_{c_2} \cdots \partial_{a_{n+1}} n_{c_{n+2}} \\ &= -i \frac{C_n}{P} \frac{2\pi}{\text{Area}(S^{n+1})} \int dt d^{n-1}x \int_0^1 du \epsilon^{c_1 \cdots c_{n+2}} n_{c_1} \partial_t n_{c_2} \cdots \partial_u n_{c_{n+2}} \end{aligned} \quad (\text{A14})$$

We note that in Eq. (A14) the dependence on $\vec{p}$ is implicitly contained in $\hat{n}(\vec{p} + \vec{\theta}(t, \vec{x}))$. By replacing $\vec{m}(\vec{p} + \vec{\theta}(t, x, u))$ with $\vec{m}(t, \vec{x}, u)$, which smoothly interpolates between $\vec{m}(t, \vec{x}, u = 0) = \vec{m}(\vec{p})$ and $\vec{m}(t, \vec{x}, u = 1) = \vec{m}(\vec{p} + \vec{\theta}(t, x))$, we obtain the following topological action upon integrating out the fermions in Eq. (1) with $\hat{n}(t, \vec{x}, u) = \vec{m}(t, \vec{x}, u)/|\vec{m}(t, \vec{x}, u)|$

$$S_{(n-1)D} = -i \frac{C_n}{P} \frac{2\pi}{\text{Area}(S^{n+1})} \int dt d^{n-1}x \int_0^1 du \epsilon^{c_1 \cdots c_{n+2}} n_{c_1} \partial_t n_{c_2} \cdots \partial_u n_{c_{n+2}}, \quad (\text{A15})$$

which is exactly the WZW term we desire!
